# Public Transport

Public transport is growing quickly in major cities around the world. Despite drawbacks, such as waiting, missed connections, and limited independence, public transport is useful in crowded cities as it is much cheaper than personal transport and reduces the number of vehicles on the road, reducing congestion, reducing pollution, and saving oil resources. Many developed countries also use eco-friendly electric vehicles, such as trams running through the city and subways and high-speed trains beneath them, which are convenient for people to move within and between cities quickly. To accomplish this, developed countries have analysed, planned, and built standardised and integrated transportation systems.

In Vietnam, the population and number of vehicles are growing rapidly, so the development of urban transport infrastructure is very urgent. However, it is also a difficult problem because the state apparatus in some places is still bureaucratic and corrupt, with partners chosen to implement projects that are slow and not reputable, causing serious wastage of public money. Hopefully, public transport will improve in the near future and become one of the main means of transportation for Vietnamese people.
